Table 1. Glossary	ɔ

This document describes a formal model of the requirements of section 5.9 of the subset 026 of the ETCS specification 3.3.0 [Eur12]. This section describes the on-sight procedure.

The model is expressed in the formal language Event-B [Abr10] and developed within the Rodin tool [Jas12]. This formalism allows an iterative modeling approach. In general, one starts with a very abstract description of the basic functionality and step-wise adds additional details until the desired level of accuracy of the model is reached. Rodin provides the necessary proof support to ensure the correctness of the refined behavior.

In this document we present an Event-B model of the procedure on-sight. We use the iUML plugin which allows for modeling in UML state-charts to create a graphical model of the procedure which is as close as possible as its description as flowchart in the section 5.9. The state machine is iteratively developed using the refinement feature of Event-B. At each refinement step, we present the reasoning for the step, together with newly introduced variables and events.

For a short introduction on Event-B and the usage of Rodin with models on github see https://github.com/openETCS/model-evaluation/blob/master/model/B-Systerel/Event_B/rodin-projects-github.pdf?raw=true

Table 1. Glossary

1 Modeling Strategy

The section 5.9 of the SRS describes the procedure on-sight, in particular it describes the sequence of mode changes, necessary driver acknowledge and train brake to enter OS mode, dependent on the current train mode.

For better understanding and to automate many tasks for state based modeling, we use the iUML plugin [?] which automatically generates Event-B code representing a state machine specification.

2 Model Overview

Figure 1 shows the structure of the Event-B model. The left column represents the abstract state machines, the right column the contexts. An arrow from one machine to another machine represents a refinement relation, an arrow from a machine to a context represents a sees relation and arrow from one context to another represents an extension relation.

The modeling starts with the very abstract possibility to establish and to terminate a communication session in the machine m0, the set of entities is defined in the context c0. This basic functionality is refined in the succeeding machines to incorporate a more detailed description of the flowchart.

3 Model Benefits

The Event-B model in Rodin has some interesting properties which are highlighted here. Some stem from the fact that Rodin is well integrated into the Eclipse platform which renders many useful plugins available, both those explicitly developed for integration with Rodin, but also other without Rodin in mind. Other interesting properties stem from the fact that Rodin and Event-B provide an extensive proof support for properties.

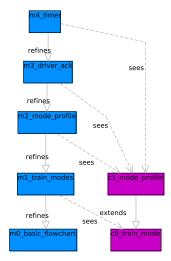

Figure 1. Overview on State Machine and Context Hierarchy

- **Graphical Modeling** Through the iUML plugin, Rodin supports graphical modeling of UML/SysML state machines. Transitions are labeled with events and a fully automatic transformation [SBS09] creates an Event-B representation of the state machine models.
- **Refinement** In addition to the general refinement which is possible in the Event-B approach, the graphical modeling allows to refine the graphical state chart models too. For each refinement step, the new details are graphically emphasized.
- Model Animation Through the ProB plugin, the graphical models can be animated just
 as textual Event-B models. In this case active transitions can be highlighted which helps
 understand model behavior.
- **Safety Properties** Using Rodin's proof support and the formalization as invariants, it is possible to formalize and prove the identified safety properties of the case study (see Section ??).

4 Detailed Model Description

This section describes in more detail the formal model, beginning from the most abstract Event-B machine. For each refinement, the state machine will be shown and in general only the important manual changes in the model generated from the state machine. The full generated code and the manual changes are available as a Rodin project. At each step the additional modeled functionality and its representation will be described. In particular the initialization event is not shown for the refined machines. If not mentioned explicitly, sets are initialized empty, integers with value 0 and Boolean variables with false.

4.1 Machine 0 - Basic Flowchart

The first state machine m0 (see Fig. 3) represents an abstract view of the flowchart describing the on-sight procedure which is shown in §5.9.7 of the SRS [Eur12] (see Fig. 2).

The flowchart is translated into a iUML state machine as follows: the initial state represents the initial situation of the procedure flowchart. The diamonds of the flowchart represent different cases and are therefore into transitions with different target states in the state chart. The nodes of the flowchart are combined for abstraction by combining nodes with multiple incoming flows (or an initial node) with direct successor nodes.

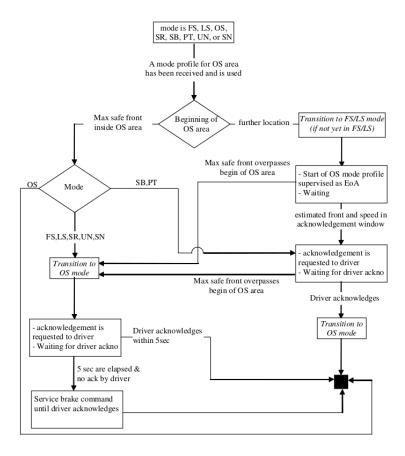

Figure 2. Flowchart for "On-Sight" Procedure [Eur12]

For example the state $ack_and_transition$ can be reached from the initial state via the event $use_profile_OS_inside_area_mode_SB_PT$ and corresponds to the two lower right nodes of the flowchart. This is justified, as the flow passes two diamonds in the flowchart, verifying that the i) max safe front of the train is inside the OS area and ii) the train mode is BS or PT. The complete model is automatically generated from this state machine. Note however, that in this abstraction level, there is no concrete notion of train modes, these appear in the first refinement.

The transitions *switch_to_OS_mode* signal the completion of the on-sight procedure, the internal switch to OS mode in the train happens elsewhere. The state *OS_mode* signals the final state.

4.2 Context 0 - Train Modes

The first context c0 specifies the possible modes of the train, these are of type t_train_modes . There is one Event-B constant for each possible mode. The constant $c_initial_mode$ represents the initial mode of the train when the procedure on-sight is started. The constant $c_supervision_mode$ is one mode from the supervision modes.

SETS

t_train_modes CONSTANTS

- c_FS full supervision
- c_LS limited supervision
- c_OS on sight
- c_SR staff responsible

\mathbf{axm3} \quad : c\_supervision\_mode \in \{c\_LS, c\_FS\}
\mathbf{END}
```

4.3 Machine 1 - Train Modes

The first machine refinement adds the variable *current_mode* which tracks the current mode of the train. This variable is initialized with the value of *c_initial_mode*.

The state of this variable is used to constrain the guards of the events that depend on the train modes, i.e., corresponding to those that lead from the "Mode" diamond in the flowchart (see Fig. 2). Its state is changed in the *transition_to_supervision_mode* event which assigns the value of *c_supervision_mode* or in the *transition_to_OS_mode* event which assigns the on-sight mode.

The refined state chart is shown in Fig. 4. The state *further_location* is refined to contain three sub-states and two events. This switches the train to supervision mode, and starts EoA supervision. The train stays in this state until either the maximal safe front passes the OS area or the estimated front and speed leave the acknowledge window. The exiting transitions are changed to originate from the *start_OS_profile_wait* state instead of its super-state. This is possible as the sub-states correctly refine the super-state.

4.4 Context 1 - Mode Profiles

This context extension introduces the type $t_mode_profile$ for mode profiles, t_train_fronts for train fronts (e.g., max safe front, estimated front), t_speed for train speed and $t_locations$ for on track locations.

The context also defines several functions, notably one which signals whether a mode profile specifies an OS area, one which signals whether a given train front overpasses the OS area for a specific mode profile, one that signals whether a train front and train speed are in the acknowledge window for a specific mode profile, one that signals whether a given train front is in the OS area of a given mode profile and finally a function that returns the EoA from a given profile.

       axm10 : c\_front0 \in t\_train\_fronts
END
```

4.5 Machine 2 - Mode Profiles

The second refinement of the machine introduces the notion of mode profiles, train fronts (max safe and estimated) and the end of authority (EoA) location into the model. These are represented by the variables EoA_loc , $mode_profile_OS$, $safe_train_front$ and $estimated_train_front$.

The train fronts can be changed by the events *update_estimated_front* and *update_safe_front*. The current values of the fronts, the current mode profile and its corresponding EoA are used as parameters for the Boolean functions that guard the events, e.g., for the event *safe_front_passes_OS_area* or for the event *front_and_speed_in_ack_window*.

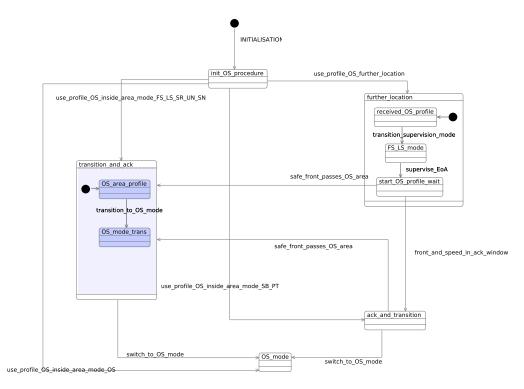

Figure 5. Second Refinement

The second refinement of the state machine is shown in Fig. 5. Here the state *transition_and_ack* is refined with two sub-states. The transition between the two new sub-states is *transition_to_OS_mode* which sets the current train mode to on-sight.

    end
END
```

4.6 Machine 3 - Driver Acknowledge

The third machine refinement introduces the driver acknowledgment. In two cases, the driver is asked to acknowledge. This is modeled by additional Boolean variables, two for acknowledging OS mode and two for acknowledging the service brake. Each time, one variable signals that the driver has been informed that he has to acknowledge, e.g., for the service brake this is the <code>currently_asking_driver_brake_ack</code> variable, and to signal the completed acknowledge there is the <code>driver_responded_brake_ack</code> variable. There is also the Boolean variable <code>service_brake</code> which signals the active service brake of the train.

The third refinement of the state machine is shown in Fig. 6. Here the two states *ack_and_transition* and *OS mode trans* are refined.

For ack_and_transition there are four new sub-states defined. There is first an event to ask the driver to acknowledge the switch to on-sight mode, then the OBU waits for the driver acknowledgment. If the max safe train front passes the OS area without driver acknowledge, then the transition_and_ack state is entered, else the train mode is switched to on-sight and the

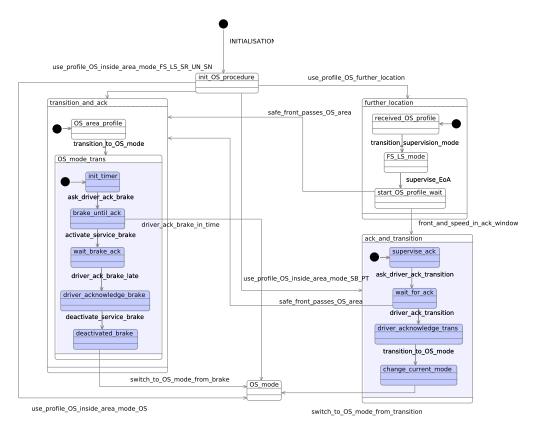

Figure 6. Third Refinement with Driver Acknowledge

final state is entered. Here the outgoing transitions from the abstract ack_and_transition state are change to originate from wait_for_ack or change_current_mode respectively. Again this is possible as the sub-states correctly refine the abstract behavior of the super state.

The abstract *OS_mode_trans* state is refined by five sub-states. First the driver is asked to acknowledge the imminent service brake. If he does so in time, then the procedure finishes and the final state is entered, else the service brake is activated and stays activated until the driver acknowledges and the final state is entered.

At this refinement stage, it is possible to prove that whenever the final state is reached, the mode of the train is on-sight (inv6).

4.7 Machine 4 - Timeout

The fourth machine refinement introduces the timer and the timeout event for the acknowledge window for the driver. This refinement is done completely in the textual model, therefore the state machine as shown in Fig. 7 is left unchanged and there is no colored highlighting.

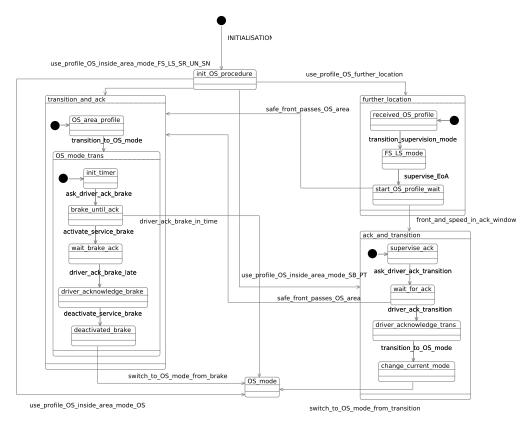

Figure 7. Fourth Refinement State Machine

The timeout is represented by the Boolean variable *timer_expired* which is modified by the *expire_timer* event. The variable is used in the guards of *driver_ack_brake_in_time*, *driver_ack_brake_late* and *activate_service_brake*.

At this refinement stage, it is possible to prove that when the timer has expired and the train has transitioned to OS mode then the transition *driver_ack_brake_in_time* cannot be enabled (*inv2*), and in the state *brake_until_ack* the transition *activate_service_brake* is enabled (*inv4*).

```

4.8 Context 2 - Speed Limits

The third context extension adds the notion of the on-sight speed limit which is represented as the constant $c_OS_speed_limit$ of type t_speed . The context also adds the function $f_speed_exceeds$ which compares two speed values and returns TRUE if the first argument exceeds the second.

```
CONTEXT c2_speed_limit
EXTENDS c1_mode_profile
CONSTANTS

c_OS_speed_limit
f_speed_exceeds

AXIOMS

axm1 : c_OS_speed_limit \in t_speed
constant OS speed limit

axm2 : f_speed_exceeds \in t_speed \times t_speed \to BOOL
f_speed_exceeds (x, y) \text{ is TRUE if speed x exceeds speed y, else FALSE}
END
```

4.9 Machine 5 - Speed Supervision

The fifth refinement of the machine adds the notion of the current speed of the train to the model. This variable can be updated by two events <code>update_train_speed_brake</code> which can only be executed when the brake is active and only accepts speed as argument which does not exceed the current speed and <code>update_train_speed_no_brake</code> which requires that the brake is not active and accepts any speed as new value.

Once active, the service brake can now only be activated if the current speed of the train does not exceed the OS speed limit.

```
MACHINE m5_speed_supervision
REFINES m4_timeout
SEES c2_speed_limit
VARIABLES

current_speed
INVARIANTS
```

```
inv2: (driver\_acknowledge\_brake = TRUE \land
                f\_speed\_exceeds(current\_speed \mapsto c\_OS\_speed\_limit) = TRUE \land
                driver\_responded\_brake\_ack = TRUE) \Rightarrow
                    service brake active = TRUE
                PROPERTY_5.9_03 driver acknowledge does not deactivate
               service brake if train speed exceeds OS speed limit
       inv10: transition_and_ack = TRUE \Rightarrow
                ((f\_speed\_exceeds(current\_speed \mapsto c\_OS\_speed\_limit) = TRUE \land
                   current\_mode = c\_OS) \Rightarrow
                   service\_brake\_active = TRUE)
                  PROPERTY_5.9_01, brake is activated if mode is OS and current speed exceeds limit
EVENTS
Event deactivate_service_brake =
extends deactivate_service_brake
    when
             grd1 : service_brake_active = TRUE
             isin_driver_acknowledge_brake : driver_acknowledge_brake = TRUE
             \verb|grd2|: f\_speed\_exceeds(current\_speed \mapsto c\_OS\_speed\_limit) = FALSE
    then
             enter_deactivated_brake : deactivated_brake := TRUE
             act2 : service\_brake\_active := FALSE
             act3 : driver_responded_brake_ack := FALSE
             leave_driver_acknowledge_brake : driver_acknowledge_brake := FALS E
Event update_train_speed_brake \widehat{=}
                                            if brake is on new speed cannot exceed current speed
    anv
            l\_speed
    where
             grd1: l\_speed \in t\_speed
             grd2 : service_brake_active = TRUE
             grd3: f\_speed\_exceeds(l\_speed \mapsto current\_speed) = FALSE
             grd4: init\_OS\_procedure = TRUE \lor OS\_mode = TRUE
    then
             act1 : current\_speed := l\_speed
Event update_train_speed_no_brake \widehat{=}
    any
            l_speed
    where
             grd1 : service\_brake\_active = FALSE
             grd2: l\_speed \in t\_speed
             grd3: driver\_acknowledge\_brake = FALSE
             grd4 : init\_OS\_procedure = TRUE \lor OS\_mode = TRUE
    then
             act1 : current_speed := l_speed
    end
END
```

At this refinement stage, it is possible to prove the two remaining safety properties from the D2.5 document: If the train is in the *driver_responded_brake_ack* state, then even if the driver has acknowledged the service brake activation, the service brake will not be deactivated if the *current_speed* exceeds the OS speed limit. And, if the train is in OS mode and the *current_speed* exceeds the speed limit, then the service brake is active.
